[001] VEHICLE EXTERNAL MIRROR ASSEMBLY AND
METHOD OF MANUFACTURE

[002] FIELD OF THE INVENTION

The present invention relates to vehicle mirror housings and in particular to vehicle external mirror housings formed from plastic.

[003] BACKGROUND OF THE INVENTION

[004] Vehicle external mirror housings have evolved from simple mounting structures for "wing mirrors" to receptacles for mirrors performing many functions and housing a number of components. For instance, mirror housings commonly house servomotors which are capable of rotating mirrors mounted to the housings about two axes so as to enable the driver to adjust his or her field of rear view. Also external mirror housings commonly are pivotable inward towards the vehicle side in the event of a collision with a solid object and, in some circumstances, automatically upon parking the vehicle to reduce the protrusions from the vehicle's side and its maximum width. Furthermore, equipment such as heaters, antennas and lights may also be supported by the modern external mirror housing. External mirror housings must also be shaped so as to minimize wind noise and so as to minimize drag, while providing an aesthetically pleasing external appearance. As a result, mirror housings have become larger, heavier, more complex and therefore more expensive to produce.

[005] To achieve the functionality and performance required at a reasonable cost, vehicle external mirror housings are usually produced in plastic using injection molding techniques. Typically housings are made from shells of injection molded plastics having wall thickness in the range of 2 to 3 millimeters. Such a wall thickness has been found to provide adequate strength and rigidity.

[006] Many different mirror housing constructions are known. Mirror housings may be formed by two mating structural components, by one cosmetic component and one structural component, or from a single cosmetic/structural component. However generally, mirror housings are produced from at least two mating components, which, when joined, form a hollow shell. Mating bosses, molded into

09890619-00001

Preferably the stiffness of said diffuser reduces from adjacent said mount to its periphery.

[013] According to a second aspect of the present invention, there is provided a vehicle external mirror assembly comprising a head; a mount for attaching said head to a vehicle; and a mirror; said head comprising an external plastic shell; a foam core, said foam anchoring and supporting said shell; and a load diffuser extending laterally into said foam core from said mount, wherein, in use, loads acting on said head are transmitted through said foam to said load diffuser.

[014] Preferably said head is pivotable with respect to said mount.

[015] Preferably the stiffness of said diffuser reduces from adjacent said mount to its periphery.

[016] According to a third aspect of the present invention, there is provided a vehicle external mirror assembly comprising a head; a mount for attaching said head to a vehicle; and a mirror; said head comprising a front molded thin external plastic shell; a rear molded thin external plastic shell meeting said front shell at a joint; and a foam core, said foam anchoring and supporting said front and rear shells. The joint may be an overlapping joint or a butt joint

[017] According to a fourth aspect of the present invention, there is provided a vehicle external mirror assembly comprising a head; a mount for attaching said head to a vehicle; and a mirror; said head comprising a front thin external plastic shell; a rear thin external plastic shell and a foam core, the foam anchoring and supporting the shell.

[018] Preferably the assembly further comprises a porous foam gasket sandwiched between edges of said front and rear shells.

[019] According to a fifth aspect of the present invention, there is provided a method for manufacturing a vehicle external mirror housing, for housing a rear vision mirror, comprising the steps of molding a first thin plastic component for use as a front shell; molding a second thin plastic component for use as a rear shell; positioning and retaining said first and second shells against each other in an edge-to-edge relationship so as to create an internal void; and substantially filling said void with foam to form a rigid assembly bonded together by said foam.

[029] Fig. 2 shows the mirror assembly of Fig. 1 in rear view;

[041] Referring to the cross sectional representations of Figs. 4 and 5, the construction of the housing is apparent. Fig. 5 shows a front molded thin external plastic shell 50 and a rear molded thin external plastic shell 60 encapsulating a

polyurethane foam core 21. The foam 21 is injected into the external plastic shell halves 50 and 60 and, when cured, bonds to the internal surfaces of shell halves 50 and 60 to secure and support them.

[042] Fig. 4, showing a cross sectional view of the mirror assembly 10 through the section lines 4-4 shown on Fig. 3, reveals a load diffuser 45. This load diffuser extends laterally into the foam core from a pivot attachment region. In use, when loads and other loads acting on the mirror housing 20 are transmitted through the foam to the load diffuser 45 and to the pivot assembly 30. The load diffuser 45 distributes forces through the foam structure thereby reducing the maximum tensile and compressive stresses within the foam 21.

[043] The vehicle external mirror assembly 10 shown in Figs. 1 to 5 differs from conventional mirrors in that foam 25 and 18 is used to provide a rigid structure and to adhere the various components together. This design enables the shells of both the vehicle bracket 15 and the mirror housing 20 to be considerably thinner. Conventional mirror shells are normally between 2 and 3 millimeters thick. In the embodiment shown in Figs. 1 to 4 the wall thickness of the shells is approximately 0.7 millimeters. Because the wall thickness is reduced, the amount of plastics material used to produce an external mirror assembly is significantly reduced. Not only does this reduce the cost, it also reduces the weight of the mirror assembly.

[044] The foam 18 and 25 used to fill the shells 17, 50 and 60 has adhesive properties which bond to the shells and thereby anchor them in position. The bonding property of the foam obviates the need for bosses and connectors between separate components.

[045] Bonding of the foam to shells and other components can be improved by providing a rough surface finish on their internal faces. This can be achieved for instance by using a mold with a grained or matt finish.

[046] Fig. 5 shows the joint between the edge 51 of the front shell 50 and the edge 61 of the rear shell 60. Figs. 7 to 13 show details of various joints that may be used between these edges 51 and 61.

[047] Fig. 7 shows an overlapping joint detail. The overlapping joint is formed from a projection 62 which extends from the edge 51 of the front shell 50 into a

FIG. 4: CROSS SECTIONAL VIEW OF THE MIRROR ASSEMBLY 10 THROUGH SECTION LINES 4-4 SHOWN ON FIG. 3.

groove 52 within the edge 61 of the rear shell 60. This joint provides positive alignment of the front shell 50 to the rear shell 60 and also presents a long leakage path to foam 21. In practice this long path has been found to be sufficient to prevent any leakage of the foam 21 from inside the void created by front shell 50 and rear shell 60 to the external surface of the shells.

[048] Fig. 8 shows an alternative jointing arrangement in which a butt joint is used. A double edge 51 abuts an edge 61 thereby forming a hidden internal chamber 57. This hidden internal chamber 57 prevents the foam 21 escaping to the exterior of the front and rear shells 50 and 60. In practice, a small amount of foam 21 will escape into the hidden internal chamber 21 but will not progress out through the joint to the exterior surface of the shells.

[049] Figs. 10, 11, 12 and 13 show a further alternative in the form of an interdigitated joint. This joint produces a "clean" joint line on the exterior while providing a very strong and positively located joint between the front shell 50 and the rear shell 60.

[050] Fig. 9 shows a fourth alternative jointing detail in which a foam gasket 70 is used between the edge 61 of the rear shell and the edge 51 of the front shell. The "sandwich" foam gasket 70 performs the function during manufacture of allowing air to escape from the void formed between the front shell 50 and the rear shell 60 while at the same time preventing foam escaping.

[051] In the above described embodiment, both the vehicle-to-mirror assembly attachment bracket 15 and the mirror housing 20 are constructed from a molded thin shell anchored (secured) and supported by foam. In alternative embodiments, the bracket 15 may be constructed in the conventional way (no foam fill).

[052] A separate colored scalp 55 as shown in Fig. 1 may be produced to fit in an aperture 54 within the front shell 50. The foam 21 acts to bond the scalp 55 securely in place. Alternatively a recess 53 may be provided in front shell 50 to accommodate a scalp which may be glued or clipped in place (refer Fig. 5). Where a detachable clip on scalp is required, access holes may be provided through the foam 21 to the rear of the mirror housing 20 (not shown).

0930649-092801
T03220-6T906360

- [053] While various plastics materials may be used to produce shell components 17, 50 and 60, ABS, ASA and polycarbonate have been found to be effective. The thickness of the plastics material can also be varied. Reduced thickness shells improves cycle times for the injection molding process and, because the foam 18 and 25 provides structural support for the mirror assembly, the rigidity and strength of the shell is of less importance. Depending on the plastic being used the thin shell will be less than 1.5 millimeters thick and usually in the range of 0.5 to 1 millimeter thick.
- [054] Various foams 18 and 21 may be used to fill the hollow shells 17, 50 and 60. Polyurethane foams are one example. The foam density, rigidity and strength properties can be varied by changing the proportion of resin and other ingredients and by selection of pressures and curing times.
- [055] Although not shown in Figs. 1 to 5, a film laminate can cover the front shell 50. This film laminate provides an aesthetically pleasing and abrasion resistant finish to the mirror housing. By including a colored film in the film laminate, the need for painting the mirror housing is eliminated. An abrasion resistant clear film covers the colored film and forms the final external layer.
- [056] The vehicle external mirror assembly described above and depicted in Figs. 1 to 5 is lightweight, rigid and of adequate strength. However the structure is not capable of withstanding high point loads and therefore it is necessary to ensure that the interface between pivot assembly 30 and on one side vehicle bracket 15 and on the other side mirror housing 20 is such that loads are diffused through the foam 18 and 21. Load transmitting members 16 and 45 perform this function. They extend away from pivot assembly 30 deep into the foam thereby distributing forces through the foam 18 and 21 respectively and reducing the maximum tensile and compressive stresses within the vehicle bracket 15 and external mirror housing 20.
- [057] The load transmitting members 16 and 45 can be designed so that their stiffness progressively reduces away from their connection points to the pivot assembly 30. This allows loads to be transferred from the relatively flexible foams 18 and 25 to the relatively rigid pivot assembly 30 while minimizing tensile

098906-19 00000000

and compressive stresses. The large surface area of load transmitting members 19 and 45 assist in ensuring a strong bond to foams 18 and 25.

[058] A first method for manufacturing a vehicle external mirror housing, for mounting a rear vision mirror, will now be described. Firstly, two thin plastic components for use as front and rear shells are injection compression molded. Secondly, these two shells are positioned and retained against each other in an edge-to-edge relationship so as to create an internal void. Finally the aforesaid void is substantially filled with foam to form a rigid assembly bonded together by the foam. Optionally a porous foam gasket, such as the gasket 70 shown in Fig. 9, can be sandwiched between the edges of the shells before the foam is injected. Such a gasket allows the escape of air but not foam from the assembly.

[059] Where load diffusers are to be used, they are placed between the two thin plastic shells before the foam is injected.

[060] It has also been found effective to create an aperture within the rear shell 60 and to then place a motor mechanism assembly component 25 within the aperture before injecting the foam (refer Fig. 1). When the foam is injected it also bonds the motor mechanism assembly 25 in position.

[061] An alternative method for manufacturing a vehicle external mirror housing, for mounting a rear vision mirror, comprises the following steps. Firstly a pre-form component is injection molded. Secondly the component is blow molded into a component having the external shape of the mirror housing. Finally the blow molded component is filled with foam to form a rigid assembly.

[062] A further method for manufacturing a vehicle external mirror housing, for mounting a rear vision mirror, introduces gas assist injection molding techniques. In this method, a first thin plastic component for use as a front shell is injection compression molded and a second thin plastic component for use as a rear shell is injection molded using gas assistance. The gas assistance produces hollow voids within the component and speeds the cooling time for the component. Having injection molded the first and second components, they are positioned against each other in an edge-to-edge relationship so as to create an internal void.

This void is then substantially filled with foam to form a rigid assembly bonded together by the foam.

[063] While the present invention has been described in terms of preferred embodiments in order to facilitate better understanding of the invention, it should be appreciated that various modifications can be made without departing from the principles of the invention. Therefore, the invention should be understood to include all such modifications within its scope.

[001]

VEHICLE EXTERNAL MIRROR ASSEMBLY AND
METHOD OF MANUFACTURE

[002]

FIELD OF THE INVENTION

The present invention relates to vehicle mirror housings and in particular to vehicle external mirror housings formed from plastic.

[003]

BACKGROUND OF THE INVENTION

[004]

Vehicle external mirror housings have evolved from simple mounting structures for "wing mirrors" to receptacles for mirrors performing many functions and housing a number of components. For instance, mirror housings commonly house servomotors which are capable of rotating mirrors mounted to the housings about two axes so as to enable the driver to adjust his or her field of rear view. Also external mirror housings commonly are pivotable inward towards the vehicle side in the event of a collision with a solid object and, in some circumstances, automatically upon parking the vehicle to reduce the protrusions from the vehicle's side and its maximum width. Furthermore, equipment such as heaters, antennas and lights may also be supported by the modern external mirror housing. External mirror housings must also be shaped so as to minimize wind noise and so as to minimize drag, while providing an aesthetically pleasing external appearance. As a result, mirror housings have become larger, heavier, more complex and therefore more expensive to produce.

[005]

To achieve the functionality and performance required at a reasonable cost, vehicle external mirror housings are usually produced in plastic using injection moulding techniques. Typically housings are made from shells of injection moulded plastics having wall thickness in the range of 2 to 3 millimetres ~~millimeters~~. Such a wall thickness has been found to provide adequate strength and rigidity.

[006]

Many different mirror housing constructions are known. Mirror housings may be formed by two mating structural components, by one cosmetic component and one structural component, or from a single cosmetic/structural component. However generally, mirror housings are produced from at least two mating

09/890619

components, which, when joined, form a hollow shell. Mating bosses, moulded into the shells are usually provided to facilitate alignment and joining of components. Within the hollow shell is provided a mount to enable connection of the mirror housing to a vehicle bracket, which itself is attached to the side of a vehicle. In order to avoid high stresses within the plastic shell, these mounts must be designed so that they distribute load away from the mount itself. This becomes increasingly important as the wall thickness of the plastics shell is reduced.

[007] Vehicle external mirror housings are generally made from shells having mounting and connection bosses which add to the complexity of the injection moulding tooling. Furthermore, the injection moulded shells, having a wall thickness of 2 to 3 ~~millimetres~~millimeters take a significant time to cool resulting in a cycle time of about 50 seconds. A reduction in wall thickness not only reduces cycle times but also reduces the amount of plastics material used, reduces the cost and reduces the weight of the mirror housing.

[008] An alternative external vehicle mirror construction for large mirrors such as those found on trucks and buses is disclosed by Canadian Patent Application No. 2198267. With this construction, a core is moulded from polyurethane foam and subsequently a reinforcing layer "a few ~~millimetres~~millimeters thick" is sprayed on. While this construction may have some advantages for large mirrors, it has the disadvantage that the surface finish is difficult to control with precision.

[009] It is an object of the present invention to provide an improved vehicle external mirror that overcomes some of the problems outlined above.

[010] SUMMARY OF THE INVENTION

[011] According to the a first aspect of present invention, there is provided a vehicle external mirror assembly comprising:— a head; —a mount for attaching said head to a vehicle; and —a mirror; —said head comprising: a moulded thin external plastic shell; and —a foam core, said foam anchoring and supporting said shell.

FOUO: 67506860

~~[015] Preferably the assembly further comprises a load diffuser extending laterally into said foam core from said mount, wherein, in use, loads acting on said head are transmitted through said foam to said load diffuser.~~

[016] or a butt joint

[0171] According to a 3rd~~fourth~~ aspect of the present invention, there is provided a vehicle external mirror assembly comprising:—a head; —a mount for attaching said head to a vehicle; and —a mirror; —said head comprising: a front-moulded thin external plastic shell; —a rear-moulded thin external plastic shell ~~meeting said front shell in an edge to edge relationship with a butt joint; and —a foam core, said foam anchoring and supporting said front and rear shells.~~

~~[017] Preferably the assembly further comprises a hidden internal chamber formed between edges of said front and rear shells for preventing foam escaping to the exterior of said shells.~~

~~[018] According to a 4th aspect of the present invention, there is provided a vehicle external mirror assembly comprising: a head; a mount for attaching said head to a vehicle; and a mirror; said head comprising: a front moulded thin external plastic shell; a rear moulded thin external plastic shell; a porous foam gasket sandwiched between edges of the front and rear shell; and and a foam core, the foam anchoring and supporting the shell.~~

[018]_ Preferably the assembly further comprises a ~~load diffuser extending laterally into said foam core from said mount, wherein, in use, loads acting on said head are transmitted through said foam to said load diffuser.~~

[020]porous foam gasket sandwiched between edges of said front and rear shells.

[019] According to a 5th fifth aspect of the present invention, there is provided a method for manufacturing a vehicle external mirror housing, for mounting housing a rear vision mirror, comprising the steps of: —moulding a first thin plastic component for use as a front shell; —moulding a second thin plastic component for use as a rear shell; —positioning and retaining thesaid first and second shells against each other in an edge-to-edge relationship so as to create an internal void; and —substantially filling thesaid void with foam to form a rigid assembly bonded together by the foam.

{024}said foam.

[020] Preferably injection compression molding is used to mold both of said front and rear thin plastic components.

[0221] Preferably the method comprises a sub-step of sandwiching a porous foam gasket between the edges of said first and second shells, whereby said gasket allows the escape of air but not foam from said void.

[0221] According to a 6th sixth aspect of the present invention, there is provided a method for manufacturing a vehicle external mirror housing, for mounting a rear vision mirror, comprising the steps of: —moulding a pre-form component; blow moulding thesaid pre-form component into a component having the external shape of a thesaid mirror housing; —substantially filling thesaid blow moulded component with foam to form a rigid assembly.

[023] According to a 7th seventh aspect of the present invention, there is provided a method for manufacturing a vehicle external mirror housing, for mountinghousing a rear vision mirror, comprising the steps of: —moulding a first thin plastic component for use as a front shell; —gas assist injection moulding a second thin plastic component for use as a rear shell; —positioning and retaining thesaid first and second shells against each other in an edge-to-edge relationship so as to create an internal void; and —substantially filling thesaid void with foam to form a rigid assembly bonded together by the foam.

~~[023]~~said foam.

[024] Preferably injection compression molding is used to mold both of said front and rear thin plastic components.

[025] Specific embodiments of the invention will now be described in some further detail with reference to and as illustrated in the accompanying figures. These embodiments are illustrative, and are not meant to be restrictive of the scope of the invention.

[026] DETAILED DESCRIPTION OF ~~PREFERRED EMBODIMENTS OF THE~~
INVENTIONDRAWINGS

[037] Figs 11-13 show an interdigitated joint at the interface between the front and rear shells of the mirror housing shown in Figs 1-5.

[040] The mount/bracket 15 and mirror head 20 shown in Figs 1 and 2 are separate components allowing a breakaway pivot assembly to be used. In some

The vehicle external mirror assembly 10 shown in Figs 1 to 5 differs from conventional mirrors in that foam 25 and 18 is used to provide a rigid structure and to adhere the various components together. This design enables the shells of both the vehicle bracket 15 and the mirror housing 20 to be considerably thinner. Conventional mirror shells are normally between 2 and 3 ~~millimetres~~millimeters thick. In the embodiment shown in Figs 1 to 4 the wall thickness of the shells is approximately 0.7 ~~millimetres~~millimeters. Because the wall thickness is reduced, the amount of plastics material used to produce an external mirror assembly is significantly reduced. Not only does this reduce the cost, it also reduces the weight of the mirror assembly.-

[044] The foam 18 and 25 used to fill the shells 17, 50 and 60 has adhesive properties which bond to the shells and thereby anchor them in position. The bonding property of the foam obviates the need for bosses and connectors between separate components.

- [045] Bonding of the foam to shells and other components can be improved by providing a rough surface finish on their internal faces. This can be achieved for instance by using a mould with a grained or matt finish.
- [046] Fig 5 shows the joint between the edge 51 of the front shell 50 and the edge 61 of the rear shell 60. Figs 7 to 13 show details of various joints that may be used between these edges 51 and 61.
- [047] Fig 7 shows an overlapping joint detail. The overlapping joint is formed from a projection 62 which extends from the edge 51 of the front shell 50 into a groove 52 within the edge 61 of the rear shell 60. This joint provides positive alignment of the front shell 50 to the rear shell 60 and also presents a long leakage path to foam 21. In practice this long path has been found to be sufficient to prevent any leakage of the foam 21 from inside the void created by front shell 50 and rear shell 60 to the external surface of the shells.
- [048] Fig 8 shows an alternative jointing arrangement in which a butt joint is used. A double edge 51 abuts an edge 61 thereby forming a hidden internal chamber 57. This hidden internal chamber 57 prevents the foam 21 escaping to the exterior of the front and rear shells 50 and 60. In practice, a small amount of foam 21 will escape into the hidden internal chamber 21 but will not progress out through the joint to the exterior surface of the shells.
- [049] Figs 10, 11, 12 and 13 show a further alternative in the form of an interdigitated joint. This joint produces a "clean" joint line on the exterior while providing a very strong and positively located joint between the front shell 50 and the rear shell 60.
- [050] Fig 9 shows a fourth alternative jointing detail in which a foam gasket 70 is used between the edge 61 of the rear shell and the edge 51 of the front shell. The "sandwich" foam gasket 70 performs the function during manufacture of allowing air to escape from the void formed between the front shell 50 and the rear shell 60 while at the same time preventing foam escaping.
- [051] In the above described embodiment, both the vehicle-to-mirror assembly attachment bracket 15 and the mirror housing 20 are constructed from a moulded

thin shell anchored (secured) and supported by foam. In alternative embodiments, the bracket 15 may be constructed in the conventional way (no foam fill).

[052] A separate coloured scalp 55 as shown in Fig 1 may be produced to fit in an aperture 54 within the front shell 50. The foam 21 acts to bond the scalp 55 securely in place. Alternatively a recess 53 may be provided in front shell 50 to accommodate a scalp which may be glued or clipped in place (refer Fig 5). Where a detachable clip on scalp is required, access holes may be provided through the foam 21 to the rear of the mirror housing 20 (not shown).

[053] While various plastics materials may be used to produce shell components 17, 50 and 60, ABS, ASA and polycarbonate have been found to be effective. The thickness of the plastics material can also be varied. Reduced thickness shells improves cycle times for the injection moulding process and, because the foam 18 and 25 provides structural support for the mirror assembly, the rigidity and strength of the shell is of less importance. Depending on the plastic being used the thin shell will be less than 1.5 ~~millimetres~~millimeters thick and usually in the range of 0.5 to 1 ~~millimetre~~millimeter thick.

[054] Various foams 18 and 21 may be used to fill the hollow shells 17, 50 and 60. Polyurethane foams are one example. The foam density, rigidity and strength properties can be varied by changing the proportion of resin and other ingredients and by selection of pressures and curing times.

[055] Although not shown in Figs 1 to 5, a film laminate can cover the front shell 50. This film laminate provides an aesthetically pleasing and abrasion resistant finish to the mirror housing. By including a coloured film in the film laminate, the need for painting the mirror housing is eliminated. An abrasion resistant clear film covers the coloured film and forms the final external layer.

[056] The vehicle external mirror assembly described above and depicted in Figs 1 to 5 is lightweight, rigid and of adequate strength. However the structure is not capable of withstanding high point loads and therefore it is necessary to ensure that the interface between pivot assembly 30 and on one side vehicle bracket 15 and on the other side mirror housing 20 is such that loads are diffused through the foam 18 and 21. Load transmitting members 16 and 45 perform this

function. They extend away from pivot assembly 30 deep into the foam thereby distributing forces through the foam 18 and 21 respectively and reducing the maximum tensile and compressive stresses within the vehicle bracket 15 and external mirror housing 20.

[057] The load transmitting members 16 and 45 can be designed so that their stiffness progressively reduces away from their connection points to the pivot assembly 30. This allows loads to be transferred from the relatively flexible foams 18 and 25 to the relatively rigid pivot assembly 30 while minimizing tensile and compressive stresses. The large surface area of load transmitting members 19 and 45 assist in ensuring a strong bond to foams 18 and 25.

[058] A first method for manufacturing a vehicle external mirror housing, for mounting a rear vision mirror, will now be described. Firstly, two thin plastic components for use as front and rear shells are injection compression moulded. Secondly, these two shells are positioned and retained against each other in an edge-to-edge relationship so as to create an internal void. Finally the aforesaid void is substantially filled with foam to form a rigid assembly bonded together by the foam. Optionally a porous foam gasket, such as the gasket 70 shown in Fig 9, can be sandwiched between the edges of the shells before the foam is injected. Such a gasket allows the escape of air but not foam from the assembly.

[059] Where load diffusers are to be used, they are placed between the two thin plastic shells before the foam is injected.

[060] It has also been found effective to create an aperture within the rear shell 60 and to then place a motor mechanism assembly component 25 within the aperture before injecting the foam (refer Fig 1). When the foam is injected it also bonds the motor mechanism assembly 25 in position.

[061] An alternative method for manufacturing a vehicle external mirror housing, for mounting a rear vision mirror, comprises the following steps. Firstly a pre-form component is injection moulded. Secondly the component is blow moulded into a component having the external shape of the mirror housing. Finally the blow moulded component is filled with foam to form a rigid assembly.

[063] While the present invention has been described in terms of preferred embodiments in order to facilitate better understanding of the invention, it should be appreciated that various modifications can be made without departing from the principles of the invention. _Therefore, the invention should be understood to include all such modifications within its scope._
